

100 Days of Linux - Day 076

Title: Viewing Network Information with ip

Today's Goal

Learn how to view network interfaces, IP addresses and routing information using the **ip** command.

Why This Matters

Linux administrators, developers and DevOps engineers use the **ip** command daily to diagnose network problems and verify system connectivity.

Command of the Day

Syntax: **ip** [object] [command]

Common examples:

ip addr

ip link

ip route

Useful options: **-br** (brief output)

Beginner Lesson

The **ip** command displays information about your computer's network settings. It shows IP addresses, network interfaces and routing information. It replaces many older networking commands.

Practice Questions

1. Display all IP addresses using the **ip** command.
2. View all network interfaces.
3. Display the routing table.
4. Show a brief summary of network interfaces.
5. Identify the name of your active network interface.

Hints

Use **ip** **addr**, **ip** **link**, **ip** **route** and **ip -br** **addr**. Carefully read the command output.

Mini Challenge

Run **ip -br** **addr**, identify your active interface and write down its IPv4 address.

Common Mistakes

Confusing interface names, overlooking inactive interfaces or typing the command incorrectly.

Did You Know?

The **ip** command is part of the **iproute2** package and has largely replaced older tools such as **ifconfig**.

Pro Tip

Use **ip -br** **addr** for a clean, easy-to-read summary of your network interfaces.

Answer Key (Instructor Only)

Q1: **ip** **addr**

Q2: **ip** **link**

Q3: **ip** **route**

Q4: **ip -br** **addr**

Q5: Check the interface marked UP with an IPv4 address.

Homework

Run the four **ip** commands from today's lesson and note the differences in their outputs.

Next Day Preview

Tomorrow is a revision quiz covering the networking commands learned so far.
