

100 Days of Linux - Day 087

Title: Package Management with apt - Introduction

Today's Goal

Learn how to update package information and install software using the **apt** command.

Why This Matters

Package management is an essential Linux skill. Developers and system administrators use apt to install, update and remove software safely.

Commands of the Day

Syntax:

```
sudo apt update
sudo apt install package_name
apt --help
```

Examples:

```
sudo apt update
sudo apt install tree
```

Beginner Lesson

The **apt** command manages software packages on Ubuntu. Before installing software, run **sudo apt update** to refresh the package list. Then install software with **sudo apt install** followed by the package name.

Practice Questions

1. Display the apt help page.
2. Update the package list.
3. Install the **tree** package.
4. Verify that tree is installed by running it.
5. View the installed version of tree using **tree --version**.

Hints

Most apt commands require **sudo**. Update the package list before installing new software.

Mini Challenge

Install the **tree** package and use it to display the directory structure of your home folder.

Common Mistakes

Skipping **apt update**, misspelling package names, or forgetting to use **sudo** when required.

Did You Know?

Ubuntu downloads software from trusted online repositories maintained by Canonical and the Ubuntu community.

Pro Tip

Always read the terminal output after installing a package to check for warnings or errors.

Answer Key (Instructor Only)

- Q1: apt --help
Q2: sudo apt update
Q3: sudo apt install tree
Q4: tree
Q5: tree --version

Homework

Install one additional package of your choice from the Ubuntu repositories and write down what it does.

Next Day Preview

Tomorrow you'll learn how to upgrade installed packages and remove software using apt.
