

100 Days of Linux - Day 088

Title: Upgrading and Removing Packages with apt

Today's Goal

Learn how to upgrade installed software and safely remove packages using the **apt** command.

Why This Matters

Keeping software updated improves security and stability, while removing unused packages keeps your Linux system clean and efficient.

Commands of the Day

Syntax:

```
sudo apt upgrade
sudo apt remove package_name
sudo apt autoremove
```

Examples:

```
sudo apt upgrade
sudo apt remove tree
sudo apt autoremove
```

Beginner Lesson

After refreshing the package list with **sudo apt update**, use **sudo apt upgrade** to install the latest versions of installed packages. If you no longer need software, remove it with **sudo apt remove**. Run **sudo apt autoremove** to delete unused dependencies.

Practice Questions

1. Upgrade all installed packages.
2. Remove the **tree** package.
3. Reinstall the **tree** package.
4. Remove unused dependencies.
5. Verify that tree is installed by checking its version.

Hints

Use **sudo** for package management commands. If you remove **tree**, install it again before checking its version.

Mini Challenge

Install a small package, remove it, reinstall it, and finally confirm it works correctly.

Common Mistakes

Running **apt upgrade** before **apt update**, removing the wrong package, or forgetting to confirm prompts.

Did You Know?

The **autoremove** command helps free disk space by deleting packages that are no longer required.

Pro Tip

Read the list of packages that will be upgraded or removed before pressing Y to continue.

Answer Key (Instructor Only)

- Q1: `sudo apt upgrade`
Q2: `sudo apt remove tree`
Q3: `sudo apt install tree`
Q4: `sudo apt autoremove`
Q5: `tree --version`

Homework

Review the installed packages on your system and practise upgrading and removing a non-essential package.

Next Day Preview

Tomorrow you'll learn how to search for packages and view package information using apt.
