

100 Days of Linux - Day 091

Title: Your First Bash Script

Today's Goal

Learn how to create, make executable and run your first Bash shell script.

Why This Matters

Shell scripts automate repetitive Linux tasks and are widely used in software development, DevOps, system administration and data engineering.

Commands of the Day

Syntax:

```
nano hello.sh
chmod +x hello.sh
./hello.sh
```

Example Script:

```
#!/bin/bash
echo "Hello, Linux!"
```

Beginner Lesson

A Bash script is a text file containing Linux commands. The first line, called the shebang (`#!/bin/bash`), tells Linux to run the script with the Bash shell. After writing the script, make it executable with **chmod +x** and run it using **./script_name**.

Practice Questions

1. Create a file named `hello.sh` using `nano`.
2. Add the shebang and an `echo` command that prints 'Hello, Linux!'.
3. Make the script executable.
4. Run the script.
5. Modify the script to print your name and run it again.

Hints

Every Bash script should begin with **#!/bin/bash**. Save the file before making it executable.

Mini Challenge

Create a script named `welcome.sh` that prints a welcome message on three separate lines.

Common Mistakes

Forgetting the shebang, not using **chmod +x**, or running the script without **./**.

Did You Know?

Many automated deployment and backup jobs on Linux are powered by simple Bash scripts.

Pro Tip

Keep scripts in a dedicated folder and use meaningful file names such as `backup.sh` or `setup.sh`.

Answer Key (Instructor Only)

- Q1: `nano hello.sh`
Q2: `#!/bin/bash` then `echo "Hello, Linux!"`
Q3: `chmod +x hello.sh`
Q4: `./hello.sh`
Q5: Edit the `echo` command, save and run `./hello.sh` again.

Homework

Create another script that prints today's date using the **date** command.

Next Day Preview

Tomorrow you'll learn how to use variables inside Bash scripts.
